ОТЧЕТ
по лабораторной работе №3
по дисциплине «Построение и анализ алгоритмов»
Тема: Максимальный поток

Студент гр. 9382

Дерюгин Д.А.

Преподаватель

Фирсов М.А.

Санкт-Петербург

2021

Цель работы.

Изучить алгоритм Форда-Фалкерсона, а также написать программу поиска максимального потока при помощи данного алгоритма.

Задание.

Вариант 6. Поиск не в глубину и не в ширину, а по правилу: каждый раз выполняется переход по дуге, соединяющей вершины, имена которых в алфавите ближе всего друг к другу. Если таких дуг несколько, то выбрать ту, имя конца которой в алфавите ближайшее к началу алфавита.

Найти максимальный поток в сети, а также фактическую величину потока, протекающего через каждое ребро, используя алгоритм Форда-Фалкерсона.

Сеть (ориентированный взвешенный граф) представляется в виде триплета из имён вершин и целого неотрицательного числа - пропускной способности (веса).

Входные данные:

N - количество ориентированных рёбер графа

v_0 - исток

v_n - сток

$v_i \ v_j \ \omega_{ij}$ - ребро графа

$v_i \ v_j \ \omega_{ij}$ - ребро графа

...

Выходные данные:

P_{max} - величина максимального потока

$v_i \ v_j \ \omega_{ij}$ - ребро графа с фактической величиной протекающего потока

$v_i \ v_j \ \omega_{ij}$ - ребро графа с фактической величиной протекающего потока

...

В ответе выходные рёбра отсортируйте в лексикографическом порядке по первой вершине, потом по второй (в ответе должны присутствовать все указанные входные рёбра, даже если поток в них равен 0).

Sample Input:

```
7
a
f
a b 7
a c 6
b d 6
c f 9
d e 3
d f 4
e c 2
```

Sample Output:

```
12
a b 6
a c 6
b d 6
c f 8
d e 2
d f 4
e c 2
```

Описание алгоритма:

Ищем путь от истока к стоку следующим образом:

Все посещенные вершины записываются в список. Среди всех этих вершин выбираем ребро, соединяющее вершины, имена которых находятся ближе друг к другу в алфавите. Если же таких ребер несколько, тогда берется ребро, имя конца которого находится ближе к началу алфавита.

После того, как алгоритм дошел до конечной вершины, ищется максимальный поток, который может пройти по данному пути (минимум из всех весов ребер на данном пути). После из каждого ребра в пути вычитается найденный минимальный поток. Алгоритм заканчивает свою работу, когда больше невозможно найти путь от истока к стоку.

Сложность:

По времени

В худшем случае, если при каждом найденном пути поток будет увеличиваться на единицу и проходить все ребра, тогда сложность по времени будет равна:

$O(F \cdot E)$, где F - максимальный поток, E - число ребер

По памяти

Граф хранит информацию о всех вершинах и ребрах, тогда сложность по памяти будет $O(V + E)$, где V – количество вершин в графе, E - количество ребер.

Описание функций и структур данных:

`class Vertex` - класс вершины графа

Поля:

`name` - имя вершины

`edges` - список ребер вершины с их весами

`visited` - переменная, которая показывает, была ли вершин посещена

`Class Graph` - класс графа

Поля:

`vertexes` - словарь, ключи которого - вершины, а значения - класс этой вершины

flow - максимальный поток, пройденный через граф

source - исток графа

sunk - сток графа

Методы класса:

def add_edge(self, name_from, name_to, weight) - метод, который добавляет новое ребро в граф, где name_from - откуда ребро исходит, name_to - куда входит ребро, weight - вес ребра.

def find_min_flow(graph) - ищет максимальный поток на одном пути из истока к стоку в графе graph

def remove_path(graph, min) - изменяет пропускные способности ребер в графе graph, где min - минимальная пропускная способность на данном пути

def start_algorithm(graph) - функция, которая реализует алгоритм.

graph - граф

def filter_vertexes(vertexes) - функция сортировки вершин в алфавитном порядке

vertexes - словарь вершин

def main() - стартовая функция, которая создает и заполняет граф

Тестирование алгоритма.

	b c 100	
	c d 1	

Выводы.

В результате выполнения работы был изучен алгоритм Форда-Фалкерсона а также написана программа, которая ищет максимальный поток в графе при помощи данного алгоритма.
